# Construction of Lower and Upper Functions and Their Application to Regular and Singular Periodic Boundary Value Problems 

Irena Rachůnková ${ }^{\text {b,1 }}$, Milan Tvrdý ${ }^{\text {a,* }}$<br>${ }^{\text {a }}$ Mathematical Institute, Academy of Sciences of the Czech Republic, 11567 PRAHA 1, Žitná 25, Czech Republic<br>${ }^{\mathrm{b}}$ Department of Mathematics, Palacký University, 77900 OLOMOUC, Tomkova 40, Czech Republic

#### Abstract

We present conditions ensuring the existence of possibly nonsmooth upper and lower functions for the periodic boundary value problem $u^{\prime \prime}=f(t, u), u(0)=u(2 \pi)$, $u^{\prime}(0)=u^{\prime}(2 \pi)$. This enables us to obtain new existence and multiplicity results for regular and singular periodic boundary value problems.

Key words: Second order nonlinear ordinary differential equation, periodic solution, singular problem, lower and upper functions, attractive and repulsive singularity, Duffing equation.
1991 MSC: 34B15, 34C25

## 1. Introduction

In the literature concerning the existence of solutions to nonlinear boundary value problems we can often find methods based on the lower and upper functions approach. See e.g. [1], [4], [6], [7], [8], [19], [20] and references therein. On the other hand, the problem of construction of lower and upper functions has been solved very rarely. In this paper we fill this gap and present conditions

[^0]ensuring the existence of nonconstant possibly nonsmooth lower and upper functions to the periodic boundary value problem
\[

$$
\begin{equation*}
u^{\prime \prime}=f(t, u), \quad u(0)=u(2 \pi), \quad u^{\prime}(0)=u^{\prime}(2 \pi) \tag{1.1}
\end{equation*}
$$

\]

and find estimates for them. This enables us to prove the existence theorem for the periodic problem for the Duffing equation with a repulsive singularity which extends the classical result of Lazer \& Solimini [10] and supplements the results obtained by some of their followers (see e.g. [2], [13] or [21]). In particular, our result is closely related to that of Omari \& Ye [13].

Throughout the paper we assume: $f:[0,2 \pi] \times \mathbb{R} \mapsto \mathbb{R}$ fulfils the Carathéodory conditions on $[0,2 \pi] \times \mathbb{R}$, i.e. $f$ has the following properties: (i) for each $x \in \mathbb{R}$ the function $f(., x)$ is measurable on $[0,2 \pi]$; (ii) for almost every $t \in[0,2 \pi]$ the function $f(t,$.$) is continuous on \mathbb{R}$; (iii) for each compact set $\mathrm{K} \subset \mathbb{R}$ the function $m_{\mathrm{K}}(t)=\sup _{x \in \mathrm{~K}}|f(t, x)|$ is Lebesgue integrable on $[0,2 \pi]$.

The set of functions $f:[0,2 \pi] \times \mathbb{R} \mapsto \mathbb{R}$ satisfying the Carathéodory conditions on $[0,2 \pi] \times \mathbb{R}$ is denoted by $\operatorname{Car}([0,2 \pi] \times \mathbb{R})$. Furthermore, we keep the following notation:

As usual, for a subset $M$ of $\mathbb{R}, \chi_{M}$ denotes the characteristic function of $M$ $\left(\chi_{M}(t)=1\right.$ for $t \in M, \chi_{M}(t)=0$ for $\left.t \in \mathbb{R} \backslash M\right)$.

For a given subinterval $J$ of $\mathbb{R}$ (possibly unbounded), $\mathbb{C}(J)$ denotes the set of functions continuous on $J$. Furthermore, $\mathbb{L}[0,2 \pi]$ stands for the set of functions Lebesgue integrable on $[0,2 \pi], \mathbb{L}_{2}[0,2 \pi]$ is the set of functions square Lebesgue integrable on $[0,2 \pi], \mathbb{A} \mathbb{C}[0,2 \pi]$ denotes the set of functions absolutely continuous on $[0,2 \pi]$ and $\mathbb{B} \mathbb{V}[0,2 \pi]$ is the set of functions of bounded variation on $[0,2 \pi]$. If $x \in \mathbb{B V}[0,2 \pi], s \in(0,2 \pi]$ and $t \in[0,2 \pi)$, then the symbols $x(s-)$, $x(t+)$ and $\Delta^{+} x(t)$ are defined respectively by

$$
x(s-)=\lim _{\tau \rightarrow s-} x(\tau), \quad x(t+)=\lim _{\tau \rightarrow t+} x(\tau) \text { and } \Delta^{+} x(t)=x(t+)-x(t)
$$

while $x^{\text {ac }}$ and $x^{\text {sing }}$ stand for the absolutely continuous part of $x$ and the singular part of $x$, respectively. We suppose $x^{\operatorname{sing}}(0)=0$. For a given $\tau \in$ $[0,2 \pi), \mathbb{A} \mathbb{C}([0,2 \pi] \backslash\{\tau\})$ is the set of functions $x \in \mathbb{B} \mathbb{V}[0,2 \pi]$ such that $x-\Delta^{+} x(\tau) \chi_{(\tau, 2 \pi]} \in \mathbb{A} \mathbb{C}[0,2 \pi]$. For $x \in \mathbb{C}[0,2 \pi], y \in \mathbb{L}[0,2 \pi]$ and $z \in \mathbb{L}_{2}[0,2 \pi]$ we denote

$$
\begin{gathered}
\|x\|_{\mathbb{C}}=\sup _{t \in[0,2 \pi]}|x(t)|, \quad \bar{y}=\frac{1}{2 \pi} \int_{0}^{2 \pi} y(s) \mathrm{d} s \\
\|y\|_{1}=\int_{0}^{2 \pi}|y(t)| \mathrm{d} t \quad \text { and } \quad\|z\|_{2}=\left(\int_{0}^{2 \pi} z^{2}(t) \mathrm{d} t\right)^{\frac{1}{2}}
\end{gathered}
$$

Finally, for a given function $\beta \in \mathbb{L}[0,2 \pi], \beta^{+}$denotes its nonnegative part $\left(\beta^{+}(t)=\max \{\beta(t), 0\}\right.$ for a.e. $\left.t \in[0,2 \pi]\right)$ and $\beta^{-}$stands for its nonpositive
$\operatorname{part}\left(\beta^{-}(t)=\max \{-\beta(t), 0\}\right.$ for a.e. $\left.t \in[0,2 \pi]\right)$.
By a solution of (1.1) we understand a function $u:[0,2 \pi] \mapsto \mathbb{R}$ such that $u^{\prime} \in \mathbb{A} \mathbb{C}[0,2 \pi], u(0)=u(2 \pi), u^{\prime}(0)=u^{\prime}(2 \pi)$ and

$$
u^{\prime \prime}(t)=f(t, u(t)) \quad \text { for a.e. } t \in[0,2 \pi] .
$$

The following definition generalizes most of the earlier ones and is taken from [15].
1.1. Definition. Functions $\left(\sigma_{1}, \rho_{1}\right) \in \mathbb{A} \mathbb{C}[0,2 \pi] \times \mathbb{B} \mathbb{V}[0,2 \pi]$ are said to be lower functions of the problem (1.1), if the singular part $\rho_{1}^{\text {sing }}$ of $\rho_{1}$ is nondecreasing on $[0,2 \pi]$,

$$
\sigma_{1}^{\prime}(t)=\rho_{1}(t), \quad \rho_{1}^{\prime}(t) \geq f\left(t, \sigma_{1}(t)\right) \quad \text { for a.e. } t \in[0,2 \pi]
$$

and

$$
\begin{equation*}
\sigma_{1}(0)=\sigma_{1}(2 \pi), \quad \rho_{1}(0)=\rho_{1}(2 \pi) \tag{1.2}
\end{equation*}
$$

Similarly, functions $\left(\sigma_{2}, \rho_{2}\right) \in \mathbb{A} \mathbb{C}[0,2 \pi] \times \mathbb{B} \mathbb{V}[0,2 \pi]$ are said to be upper functions of the problem (1.1), if the singular part $\rho_{2}^{\text {sing }}$ of $\rho_{2}$ is nonincreasing on $[0,2 \pi]$,

$$
\sigma_{2}^{\prime}(t)=\rho_{2}(t), \quad \rho_{2}^{\prime}(t) \leq f\left(t, \sigma_{2}(t)\right) \quad \text { for a.e. } t \in[0,2 \pi]
$$

and

$$
\begin{equation*}
\sigma_{2}(0)=\sigma_{2}(2 \pi), \quad \rho_{2}(0)=\rho_{2}(2 \pi) \tag{1.3}
\end{equation*}
$$

For the existence results obtained in this paper we will need the following theorem which is contained in [15, Theorems 4.1 and 4.2].
1.2. Theorem. Let $\left(\sigma_{1}, \rho_{1}\right)$ and $\left(\sigma_{2}, \rho_{2}\right)$ be respectively lower and upper functions of the problem (1.1).
(I) Suppose $\sigma_{1}(t) \leq \sigma_{2}(t)$ on $[0,2 \pi]$. Then there is a solution $u$ of the problem (1.1) such that $\sigma_{1}(t) \leq u(t) \leq \sigma_{2}(t)$ on $[0,2 \pi]$.
(II) Suppose $\sigma_{1}(t) \geq \sigma_{2}(t)$ on $[0,2 \pi]$ and there is $m \in \mathbb{L}[0,2 \pi]$ such that

$$
f(t, x) \geq m(t)(\text { or } f(t, x) \leq m(t)) \text { for a.e. } t \in[0,2 \pi] \text { and all } x \in \mathbb{R}
$$

Then there is a solution $u$ of the problem (1.1) such that $\left\|u^{\prime}\right\|_{\mathbb{C}} \leq\|m\|_{1}$ and

$$
\sigma_{2}\left(t_{u}\right) \leq u\left(t_{u}\right) \leq \sigma_{1}\left(t_{u}\right) \quad \text { for some } t_{u} \in[0,2 \pi]
$$

## 2. Construction of lower and upper functions

Let us consider an auxiliary boundary value problem

$$
\begin{gather*}
\sigma^{\prime}=\rho, \quad \rho^{\prime}=\beta(t)  \tag{2.1}\\
\sigma(0)=\sigma(2 \pi)=c, \quad \rho(0)=\rho(2 \pi), \Delta^{+} \rho(\tau)=-2 \pi \bar{\beta} \tag{2.2}
\end{gather*}
$$

where $\beta \in \mathbb{L}[0,2 \pi]$ and $c \in \mathbb{R}$.
2.1. Definition. Let $\tau \in[0,2 \pi), c \in \mathbb{R}$ and $\beta \in \mathbb{L}[0,2 \pi]$ be given. By a solution of the problem (2.1), (2.2) we mean a couple of functions $(\sigma, \rho) \in$ $\mathbb{A} \mathbb{C}[0,2 \pi] \times \mathbb{A} \mathbb{C}([0,2 \pi] \backslash\{\tau\})$ satisfying (2.2) and

$$
\begin{equation*}
\sigma^{\prime}(t)=\rho(t), \quad \rho^{\prime}(t)=\beta(t) \quad \text { a.e. on }[0,2 \pi] . \tag{2.3}
\end{equation*}
$$

2.2. Proposition. Let $c \in \mathbb{R}, \tau \in[0,2 \pi)$ and $\beta \in \mathbb{L}[0,2 \pi]$. Then the problem (2.1), (2.2) possesses a unique solution $(\sigma, \rho)$. Moreover, $\rho^{s i n g}=-2 \pi \bar{\beta} \chi_{(\tau, 2 \pi]}$ and $\sigma$ is given by

$$
\begin{equation*}
\sigma(t)=c-g(t, \tau)(2 \pi \bar{\beta})+\int_{0}^{2 \pi} g(t, s) \beta(s) \mathrm{d} s \text { on }[0,2 \pi] \tag{2.4}
\end{equation*}
$$

where

$$
g(t, s)= \begin{cases}\frac{t(s-2 \pi)}{2 \pi} & \text { if } 0 \leq t \leq s \leq 2 \pi  \tag{2.5}\\ \frac{(t-2 \pi) s}{2 \pi} & \text { if } 0 \leq s<t \leq 2 \pi\end{cases}
$$

Proof. For $c, c_{1} \in \mathbb{R}$, put

$$
\sigma(t)=\left\{\begin{array}{cc}
c+c_{1} t+\int_{0}^{t}(t-s) \beta(s) \mathrm{d} s & \text { if } 0 \leq t \leq \tau \leq 2 \pi  \tag{2.6}\\
c+c_{1}(t-2 \pi)-\int_{t}^{2 \pi}(t-s) \beta(s) \mathrm{d} s & \text { if } 0 \leq \tau<t \leq 2 \pi
\end{array}\right.
$$

and

$$
\rho(t)=\left\{\begin{array}{lc}
c_{1}+\int_{0}^{t} \beta(s) \mathrm{d} s & \text { if } 0 \leq t \leq \tau \leq 2 \pi  \tag{2.7}\\
c_{1}-\int_{t}^{2 \pi} \beta(s) \mathrm{d} s & \text { if } \\
0 \leq \tau<t \leq 2 \pi
\end{array}\right.
$$

Then $\sigma$ and $\rho$ belong to $\mathbb{A C}([0,2 \pi] \backslash\{\tau\})$ and satisfy (2.3) and (2.2). Furthermore, $\Delta^{+} \sigma(\tau)=0$ (i.e. $\sigma$ is absolutely continuous on $[0,2 \pi]$ ) if and only if

$$
\begin{equation*}
c_{1}=-\int_{0}^{2 \pi} \frac{\tau-s}{2 \pi} \beta(s) \mathrm{d} s \tag{2.8}
\end{equation*}
$$

while $c \in \mathbb{R}$ may be arbitrary. Inserting (2.8) into (2.6) we can check that $\sigma$ verifies (2.4). Finally, in virtue of (2.7) we have

$$
\rho(t)+2 \pi \bar{\beta} \chi_{(\tau, 2 \pi]}(t)=c_{1}+\int_{0}^{t} \beta(s) \mathrm{d} s
$$

i.e. $\rho^{\text {ac }}=\rho+2 \pi \bar{\beta} \chi_{(\tau, 2 \pi]}$ and $\rho^{\text {sing }}=-2 \pi \bar{\beta} \chi_{(\tau, 2 \pi]}$.
2.3. Remark. Notice that if the couple $(\sigma, \rho)$ is determined by Proposition 2.2 , then $\rho \in \mathbb{A} \mathbb{C}[0,2 \pi]$ whenever $\bar{\beta}=0$. Furthermore, if $\bar{\beta}=0$ or $\tau=0$, then the formula (2.4) reduces to

$$
\sigma(t)=c+\int_{0}^{2 \pi} g(t, s) \beta(s) \mathrm{d} s \text { on }[0,2 \pi] .
$$

The following lemma will be often used in this paper.
2.4. Lemma. Let $u \in \mathbb{A} \mathbb{C}[0,2 \pi]$ and $u^{\prime} \in \mathbb{L}_{2}[0,2 \pi]$. Then

$$
\begin{equation*}
\|u\|_{2} \leq 2\left\|u^{\prime}\right\|_{2} \tag{2.9}
\end{equation*}
$$

holds whenever $u(0)=u(2 \pi)=0$ and

$$
\begin{equation*}
\|u\|_{2} \leq\left\|u^{\prime}\right\|_{2} \tag{2.10}
\end{equation*}
$$

and

$$
\begin{equation*}
\|u\|_{\mathbb{C}} \leq \sqrt{\frac{\pi}{6}}\left\|u^{\prime}\right\|_{2} \tag{2.11}
\end{equation*}
$$

are true whenever $u(0)=u(2 \pi)$ and $\bar{u}=0$.

Proof. The inequality (2.9) is due to Scheeffer [18, p. 207] (see also [12, II.2]). For (2.10) (Wirtinger's inequality) and (2.11) (Sobolev's inequality) see e.g. [11, Proposition 1.3]).
2.5. Proposition. Assume that there are $a, A \in \mathbb{R}, \tau \in[0,2 \pi)$ and $b \in$ $\mathbb{L}[0,2 \pi]$ such that

$$
\begin{equation*}
a \leq 0, \quad \bar{b}=0 \tag{2.12}
\end{equation*}
$$

and

$$
\begin{equation*}
f(t, x) \leq a+b(t) \text { for a.e. } t \in[0,2 \pi] \text { and all } x \in[A(t), B(t)] \tag{2.13}
\end{equation*}
$$

where

$$
\begin{equation*}
A(t)=A+a h(t, \tau), B(t)=A(t)+\frac{\pi}{3}\|b\|_{1} \quad \text { for } t \in[0,2 \pi] \tag{2.14}
\end{equation*}
$$

and

$$
h(t, \tau)= \begin{cases}\frac{t(2 \pi-2 \tau+t)}{2} & \text { if } 0 \leq t \leq \tau \leq 2 \pi  \tag{2.15}\\ \frac{(2 \pi-t)^{(2 \tau-t)}}{2} & \text { if } 0 \leq \tau \leq t \leq 2 \pi\end{cases}
$$

Then there exist lower functions $(\sigma, \rho)$ of (1.1) such that

$$
\begin{equation*}
A(t) \leq \sigma(t) \leq B(t) \text { on }[0,2 \pi] \quad \text { and } \quad \rho \in \mathbb{A} \mathbb{C}([0,2 \pi] \backslash\{\tau\}) \tag{2.16}
\end{equation*}
$$

Proof. By Proposition 2.2, the problem (2.1), (2.2) with $\beta(t)=a+b(t)$ a.e. on $[0,2 \pi]$ has a unique solution $(\sigma, \rho)$ for any $c \in \mathbb{R}$. Moreover, with respect to (2.4), (2.5) and (2.15), $\sigma$ has the form

$$
\begin{aligned}
\sigma(t) & =c-2 \pi a g(t, \tau)+\frac{a}{2} t(t-2 \pi)+\int_{0}^{2 \pi} g(t, s) b(s) \mathrm{d} s \\
& =c+a h(t, \tau)+\int_{0}^{2 \pi} g(t, s) b(s) \mathrm{d} s \text { on }[0,2 \pi] .
\end{aligned}
$$

Let us put

$$
c_{0}=-\frac{1}{2 \pi} \int_{0}^{2 \pi}\left(\int_{0}^{2 \pi} g(t, s) b(s) \mathrm{d} s\right) \mathrm{d} t
$$

and

$$
\sigma_{0}(t)=c_{0}+\int_{0}^{2 \pi} g(t, s) b(s) \mathrm{d} s \quad \text { for } t \in[0,2 \pi]
$$

Then $\overline{\sigma_{0}}=0$ and $\sigma_{0}^{\prime \prime}(t)=b(t)$ a.e. on $[0,2 \pi]$. Multiplying the last relation by $\sigma_{0}$, integrating it over $[0,2 \pi]$ and using the Hölder inequality we get $\left\|\sigma_{0}^{\prime}\right\|_{2}^{2} \leq$ $\|b\|_{1}\left\|\sigma_{0}\right\|_{\mathbb{C}}$. Further, the Sobolev inequality (2.11) (see Lemma 2.4) yields

$$
\left\|\sigma_{0}^{\prime}\right\|_{2}^{2} \leq \sqrt{\frac{\pi}{6}}\|b\|_{1}\left\|\sigma_{0}^{\prime}\right\|_{2}
$$

and so $\left\|\sigma_{0}^{\prime}\right\|_{2} \leq \sqrt{\frac{\pi}{6}}\|b\|_{1}$, wherefrom using again (2.11) we get

$$
\begin{equation*}
\left\|\sigma_{0}\right\|_{\mathbb{C}} \leq \frac{\pi}{6}\|b\|_{1} \tag{2.17}
\end{equation*}
$$

This implies that

$$
a h(t, \tau)-\frac{\pi}{6}\|b\|_{1} \leq a h(t, \tau)+\sigma_{0}(t) \leq a h(t, \tau)+\frac{\pi}{6}\|b\|_{1} \text { on } \quad[0,2 \pi] .
$$

Now, if we choose $c=c_{0}+\frac{\pi}{6}\|b\|_{1}+A$, then we get

$$
\begin{aligned}
\sigma(t) & =c+a h(t, \tau)+\int_{0}^{2 \pi} g(t, s) b(s) \mathrm{d} s \\
& =\frac{\pi}{6}\|b\|_{1}+A+a h(t, \tau)+\sigma_{0}(t) \quad \text { for } t \in[0,2 \pi]
\end{aligned}
$$

i.e., with respect to (2.17), we have

$$
A+a h(t, \tau) \leq \sigma(t) \leq A+a h(t, \tau)+\frac{\pi}{3}\|b\|_{1} \text { on }[0,2 \pi]
$$

which means that (2.16) holds. According to (2.12) and (2.13) this implies that

$$
\rho^{\prime}(t)=a+b(t) \geq f(t, \sigma(t)) \text { for a.e. } t \in[0,2 \pi] .
$$

Furthermore, with respect to (2.2) we have $\sigma(0)=\sigma(2 \pi)$ and $\rho(0)=\rho(2 \pi)$ and hence, by Definition 1.1 the functions $(\sigma, \rho)$ are lower functions of (1.1).
2.6. Remark. Notice that the function $h$ defined in (2.15) fulfils the estimates

$$
-\frac{\pi^{2}}{2} \leq-\frac{(\pi-\tau)^{2}}{2} \leq h(t, \tau) \leq \frac{\tau(2 \pi-\tau)}{2} \leq \frac{\pi^{2}}{2}
$$

on $[0,2 \pi] \times[0,2 \pi]$.

The following assertion is dual to Proposition 2.5 and its proof can be omitted.
2.7. Proposition. Assume that there are $a, A \in \mathbb{R}, \tau \in[0,2 \pi)$ and $b \in$ $\mathbb{L}[0,2 \pi]$ such that $a \geq 0, \bar{b}=0$,

$$
f(t, x) \geq a+b(t) \text { for a.e. } t \in[0,2 \pi] \text { and all } x \in[A(t), B(t)],
$$

where $A(t)$ and $B(t)$ are defined by (2.14) and (2.15).
Then there exist upper functions $(\sigma, \rho)$ of (1.1) fulfilling (2.16).

Theorems 2.8 and 2.11 and Corollary 2.9 are simple examples of existence results which follow immediately from Theorem 1.2 and Propositions 2.5 and 2.7.
2.8. Theorem. Assume that there are $A_{1}, A_{2}, a_{1}, a_{2} \in \mathbb{R}, \tau_{1}, \tau_{2} \in[0,2 \pi]$ and $b_{1}, b_{2} \in \mathbb{L}[0,2 \pi]$ such that

$$
\begin{align*}
& \begin{array}{l}
a_{1} \leq 0, \quad \overline{b_{1}}=0, \\
f(t, x) \leq a_{1}+b_{1}(t) \\
\quad \text { for a.e. } t \in[0,2 \pi] \text { and all } x \in\left[A_{1}+a_{1} h\left(t, \tau_{1}\right), B_{1}+a_{1} h\left(t, \tau_{1}\right)\right], \\
a_{2} \geq 0, \quad \overline{b_{2}}=0, \\
f(t, x) \geq a_{2}+b_{2}(t) \\
\quad \text { for a.e. } t \in[0,2 \pi] \text { and all } x \in\left[A_{2}+a_{2} h\left(t, \tau_{2}\right), B_{2}+a_{2} h\left(t, \tau_{2}\right)\right] \\
\text { and }
\end{array} \tag{2.18}
\end{align*}
$$

$$
\begin{equation*}
A_{2}+a_{2} h\left(t, \tau_{2}\right) \geq B_{1}+a_{1} h\left(t, \tau_{1}\right) \quad \text { for all } t \in[0,2 \pi], \tag{2.22}
\end{equation*}
$$

where

$$
\begin{equation*}
B_{1}-A_{1}=\frac{\pi}{3}\left\|b_{1}\right\|_{1}, \quad B_{2}-A_{2}=\frac{\pi}{3}\left\|b_{2}\right\|_{1} \tag{2.23}
\end{equation*}
$$

and $h(t, \tau)$ is given by (2.15).
Then the problem (1.1) possesses a solution $u$ such that

$$
A_{1}+a_{1} h\left(t, \tau_{1}\right) \leq u(t) \leq B_{2}+a_{2} h\left(t, \tau_{2}\right) \text { on }[0,2 \pi]
$$

2.9. Corollary. Assume that there are $A_{1}, A_{2} \in \mathbb{R}, a_{1}<0$ and $\tau_{1} \in[0,2 \pi]$ such that

$$
f\left(t, A_{1}+a_{1} h\left(t, \tau_{1}\right)\right) \leq a_{1}, \quad f\left(t, A_{2}\right) \geq 0 \quad \text { for a.e. } t \in[0,2 \pi]
$$

and

$$
A_{2} \geq A_{1}+a_{1} h\left(t, \tau_{1}\right) \quad \text { for all } t \in[0,2 \pi]
$$

where $h(t, \tau)$ is given by (2.15).
Then the problem (1.1) possesses a solution $u$ such that

$$
A_{1}+a_{1} h\left(t, \tau_{1}\right) \leq u(t) \leq A_{2} \text { on }[0,2 \pi] .
$$

2.10. Example. Let $\varepsilon>0, \eta>0, \delta>0, k_{1}>0, A_{1}>0, a_{1}<0$,

$$
q(t)= \begin{cases}A_{1}-k_{1} t & \text { if } t \in[0, \pi] \\ A_{1}+k_{1}(t-2 \pi) & \text { if } t \in(\pi, 2 \pi]\end{cases}
$$

and let $f(t, x)$ for $t \in[0,2 \pi]$ be given by

$$
f(t, x)= \begin{cases}\varepsilon & \text { if } x \leq q(t)-\eta \\ a_{1}-\frac{\varepsilon-a_{1}}{\eta}(x-q(t)) & \text { if } x \in(q(t)-\eta, q(t)], \\ a_{1} & \text { if } x \in(q(t), q(t)+\delta], \\ a_{1}+\frac{\varepsilon-a_{1}}{\eta}(x-q(t)-\delta) & \text { if } x \in(q(t)+\delta, q(t)+\delta+\eta], \\ \varepsilon & \text { if } x>q(t)+\delta+\eta .\end{cases}
$$

Then $f \in \operatorname{Car}([0,2 \pi] \times \mathbb{R})$ fulfils the assumptions of Corollary 2.9 e.g. for $A_{1}=6, a_{1}=-1, \eta=0.5, k_{1}=\frac{A_{1}-h(\pi, \pi)}{\eta}, \delta=1.28, \varepsilon$ arbitrary positive and $A_{2} \geq A_{1}+\eta$.
2.11. Theorem. Assume that there are $A_{1}, A_{2}, a_{1}, a_{2} \in \mathbb{R}, \tau_{1}, \tau_{2} \in[0,2 \pi]$ and $b_{1}, b_{2} \in \mathbb{L}[0,2 \pi]$ such that (2.18)-(2.21) and (2.23) are true and

$$
\begin{equation*}
A_{1}+a_{1} h\left(t, \tau_{1}\right) \geq B_{2}+a_{2} h\left(t, \tau_{2}\right) \quad \text { for all } t \in[0,2 \pi] . \tag{2.24}
\end{equation*}
$$

Furthermore, let there exist $m \in \mathbb{L}[0,2 \pi]$ such that

$$
\begin{align*}
& f(t, x) \geq m(t)(\text { or } f(t, x) \leq m(t))  \tag{2.25}\\
& \quad \text { for a.e. } t \in[0,2 \pi] \text { and all } x \in \mathbb{R} .
\end{align*}
$$

Then the problem (1.1) possesses a solution $u$ such that $\left\|u^{\prime}\right\|_{\mathbb{C}} \leq\|m\|_{1}$ and

$$
A_{2}+a_{2} h\left(t_{u}, \tau_{2}\right) \leq u\left(t_{u}\right) \leq B_{1}+a_{1} h\left(t_{u}, \tau_{1}\right) \quad \text { for some } t_{u} \in[0,2 \pi]
$$

## 3. Periodic problems with strong singularity

We will consider the following singular Duffing equation with periodic conditions

$$
\begin{equation*}
u^{\prime \prime}-g(u)=e(t), \quad u(0)=u(2 \pi), \quad u^{\prime}(0)=u^{\prime}(2 \pi) \tag{3.1}
\end{equation*}
$$

where

$$
\begin{equation*}
g \in \mathbb{C}(0, \infty) \quad \text { and } \quad e \in \mathbb{L}[0,2 \pi] \tag{3.2}
\end{equation*}
$$

and $g$ has strong singularity at 0 , i.e.

$$
\begin{equation*}
\lim _{x \rightarrow 0+} \int_{x}^{1} g(\xi) \mathrm{d} \xi=\infty \tag{3.3}
\end{equation*}
$$

Classical Lazer and Solimini's considerations [10] concerning the problem (3.1) have been extended by several authors (see e.g. [2], [3], [5], [9], [13], [16], [17] and [21]). Provided $g \in \mathbb{C}(0, \infty)$, $e$ is essentially bounded on $[0,2 \pi]$ and under the assumptions (3.3),

$$
\begin{align*}
& \lim _{x \rightarrow 0+} g(x)=\infty  \tag{3.4}\\
& \liminf _{x \rightarrow \infty} \frac{g(x)}{x} \geq-\frac{1}{4}, \quad \liminf _{x \rightarrow \infty} \frac{1}{x^{2}} \int_{1}^{x} g(\xi) \mathrm{d} \xi>-\frac{1}{8} \\
& \text { there is } d>0 \text { such that } g(x) \leq-\bar{e} \text { for all } x \in[d, \infty)
\end{align*}
$$

Omari and Ye proved the existence of a solution to (3.1) in [13, Theorem 1.2]. In [16, Theorem 3.2] we showed a related result, where $e$ need not be essentially bounded and (3.4) need not be fulfilled. Here we generalize the result of [16] for functions $g$ unbounded from below.
3.1. Theorem. Assume (3.2), (3.3),

$$
\begin{equation*}
\liminf _{x \rightarrow 0+} g(x)>-\infty \tag{3.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\liminf _{x \rightarrow \infty} \frac{g(x)}{x}>-\frac{1}{4} \tag{3.6}
\end{equation*}
$$

Furthermore, let there exist $A_{1}, A_{2} \in(0, \infty)$ such that

$$
\begin{gather*}
g(x) \leq-\bar{e} \quad \text { for all } x \in\left[A_{1}, B_{1}\right]  \tag{3.7}\\
g(x) \geq-\bar{e} \quad \text { for all } x \in\left[A_{2}, B_{2}\right] \tag{3.8}
\end{gather*}
$$

where

$$
\begin{equation*}
B_{1}-A_{1}=B_{2}-A_{2}=\frac{\pi}{3}\|e-\bar{e}\|_{1} \tag{3.9}
\end{equation*}
$$

and $A_{1} \geq B_{2}$.
Then the problem (3.1) has a positive solution.
3.2. Remark. Notice that if $g \in \mathbb{C}(0, \infty)$ satisfies (3.3) then

$$
\limsup _{x \rightarrow 0+} g(x)=\infty
$$

which implies the existence of a sequence $\left\{\varepsilon_{n}\right\}_{n=1}^{\infty} \subset(0,1)$ such that

$$
\begin{equation*}
g\left(\varepsilon_{n}\right)>0 \quad \text { for all } n \in \mathbb{N}, \quad \lim _{n} \varepsilon_{n}=0, \quad \lim _{n} g\left(\varepsilon_{n}\right)=\infty \tag{3.10}
\end{equation*}
$$

For the proof of Theorem 3.1 we will need the following two lemmas, where we deal with the auxiliary family of problems

$$
\begin{equation*}
u^{\prime \prime}=g_{n}(u)+e(t), \quad u(0)=u(2 \pi), \quad u^{\prime}(0)=u^{\prime}(2 \pi), \tag{3.11}
\end{equation*}
$$

where $n \in \mathbb{N}$,

$$
g_{n}(x)=\left\{\begin{array}{cl}
0 & \text { if } x<0  \tag{3.12}\\
g\left(\varepsilon_{n}\right) \frac{x}{\varepsilon_{n}} & \text { if } x \in\left[0, \varepsilon_{n}\right] \\
g(x) & \text { if } x>\varepsilon_{n}
\end{array}\right.
$$

and $\varepsilon_{n}$ are from (3.10).
3.3. Lemma. Assume that $g \in \mathbb{C}(0, \infty)$ satisfies (3.3), (3.5) and (3.6) and let $g_{n}, n \in \mathbb{N}$, be given by (3.12). Then there exist $\eta \in\left(0, \frac{1}{4}\right)$ and $C \geq 0$ such that

$$
\begin{equation*}
g_{n}(x) x \geq-\left(\frac{1}{4}-\eta\right) x^{2}-C|x| \quad \text { for all } x \in \mathbb{R} \text { and all } n \in \mathbb{N} \tag{3.13}
\end{equation*}
$$

Proof. By (3.6), there are $\eta \in\left(0, \frac{1}{4}\right)$ and $A \in(1, \infty)$ such that

$$
\begin{equation*}
\frac{g(x)}{x} \geq-\left(\frac{1}{4}-\eta\right) \quad \text { for all } x \geq A \tag{3.14}
\end{equation*}
$$

Put

$$
p(x)=\left\{\begin{array}{cl}
0 & \text { if } x<0  \tag{3.15}\\
g(A) \frac{x}{A} & \text { if } x \in[0, A] \\
g(x) & \text { if } x>A
\end{array}\right.
$$

and $q_{n}(x)=g_{n}(x)-p(x)$ on $\mathbb{R}$. In virtue of (3.5), there is $C \geq 0$ such that $q_{n}(x) \geq-C$ for all $x \in \mathbb{R}$ and all $n \in \mathbb{N}$. Thus, since according to (3.14) and (3.15) we also have

$$
p(x) \geq-\left(\frac{1}{4}-\eta\right) x \quad \text { for all } x \in[0, \infty)
$$

we deduce that (3.13) is true.
3.4. Lemma. Assume that $g$ and $g_{n}, n \in \mathbb{N}$, are as in Lemma 3.3. Then for any $r>0$ and any $e \in \mathbb{L}[0,2 \pi]$ there exists $R>0$ such that

$$
\begin{equation*}
u(t) \leq R \text { on }[0,2 \pi] \tag{3.16}
\end{equation*}
$$

holds for all $n \in \mathbb{N}$ and all solutions $u$ of (3.11) with the property

$$
\begin{equation*}
\min _{t \in[0,2 \pi]} u(t) \leq r \tag{3.17}
\end{equation*}
$$

Proof. Assume that (3.16) does not hold. Then we can choose a subsequence $\left\{g_{k}\right\}_{k=1}^{\infty}$ of the sequence $\left\{g_{n}\right\}_{n=1}^{\infty}$ and a sequence of solutions $\left\{u_{k}\right\}_{k=1}^{\infty}$ of the corresponding problems (3.11) satisying (3.17) and

$$
\begin{equation*}
\lim _{k} \max _{t \in[0,2 \pi]} u_{k}(t)=\infty \tag{3.18}
\end{equation*}
$$

In particular, for any $k \in \mathbb{N}$, there is $t_{k} \in[0,2 \pi]$ such that

$$
u_{k}\left(t_{k}\right)=r
$$

Furthermore, if we extend the functions $u_{k}, k \in \mathbb{N}$, and $e$ to functions $2 \pi$ periodic on $\mathbb{R}$, we get that

$$
\begin{equation*}
u_{k}^{\prime \prime}(t)=g_{k}\left(u_{k}(t)\right)+e(t) \text { for a.e. } t \in \mathbb{R} \tag{3.19}
\end{equation*}
$$

is true for any $k \in \mathbb{N}$.

On the other hand, if we multiply (3.19) by $u_{k}(t)$, integrate from $t_{k}$ to $t_{k}+2 \pi$ and take into account Lemma 3.3, we get that there exist $\eta \in\left(0, \frac{1}{4}\right)$ and $C>0$ such that for any $k \in \mathbb{N}$

$$
\begin{aligned}
\left\|u_{k}^{\prime}\right\|_{2}^{2} & =-\int_{t_{k}}^{t_{k}+2 \pi} g_{k}\left(u_{k}(s)\right) u_{k}(s) \mathrm{d} s-\int_{t_{k}}^{t_{k}+2 \pi} e(s) u_{k}(s) \mathrm{d} s \\
& \leq\left(\frac{1}{4}-\eta\right)\left\|u_{k}\right\|_{2}^{2}+C\left\|u_{k}\right\|_{1}+\|e\|_{1}\left\|u_{k}\right\|_{\mathbb{C}}
\end{aligned}
$$

holds. Furthermore,

$$
\begin{equation*}
\left\|u_{k}\right\|_{\mathbb{C}} \leq\left|u_{k}\left(t_{k}\right)\right|+\int_{t_{k}}^{t_{k}+2 \pi}\left|u_{k}^{\prime}(s)\right| \mathrm{d} s=r+\sqrt{2 \pi}\left\|u_{k}^{\prime}\right\|_{2} \tag{3.20}
\end{equation*}
$$

Thus,

$$
\begin{equation*}
\left(\left\|u_{k}^{\prime}\right\|_{2}-\|e\|_{1} \sqrt{\frac{\pi}{2}}\right)^{2} \leq\left(\frac{1}{4}-\eta\right)\left\|u_{k}\right\|_{2}^{2}+\sqrt{2 \pi} C\left\|u_{k}\right\|_{2}+\|e\|_{1} r+\frac{\pi}{2}\|e\|_{1}^{2} \tag{3.21}
\end{equation*}
$$

Inserting $u_{k}(t) \equiv v_{k}(t)+r$ on $\mathbb{R}$ into (3.21), we obtain

$$
\begin{equation*}
\frac{\left(\left\|v_{k}^{\prime}\right\|_{2}-c\right)^{2}}{\left\|v_{k}\right\|_{2}^{2}} \leq \frac{1}{4}-\eta+\frac{a}{\left\|v_{k}\right\|_{2}}+\frac{b}{\left\|v_{k}\right\|_{2}^{2}} \tag{3.22}
\end{equation*}
$$

where $a, b, c \in \mathbb{R}$ do not depend on $k$. Now, (3.18), (3.20) and (3.21) yield

$$
\begin{equation*}
\lim _{k}\left\|v_{k}^{\prime}\right\|_{2}=\infty \quad \text { and } \quad \lim _{k}\left\|v_{k}\right\|_{2}=\infty \tag{3.23}
\end{equation*}
$$

Since $v_{k}\left(t_{k}\right)=v\left(t_{k}+2 \pi\right)=0$, by Scheeffer's inequality (2.9) we have

$$
\left\|v_{k}\right\|_{2}^{2} \leq 4\left\|v_{k}^{\prime}\right\|_{2}^{2}
$$

and

$$
\frac{\left(\left\|v_{k}^{\prime}\right\|_{2}-c\right)^{2}}{\left\|v_{k}\right\|_{2}^{2}} \geq \frac{\left(\left\|v_{k}^{\prime}\right\|_{2}-c\right)^{2}}{4\left\|v_{k}^{\prime}\right\|_{2}^{2}}
$$

Therefore by virtue of (3.22) and (3.23) we have

$$
\frac{1}{4}=\lim _{k} \frac{\left(\left\|v_{k}^{\prime}\right\|_{2}-c\right)^{2}}{4\left\|v_{k}^{\prime}\right\|_{2}^{2}} \leq \lim _{k}\left(\frac{1}{4}-\eta+\frac{a}{\left\|v_{k}\right\|_{2}}+\frac{b}{\left\|v_{k}\right\|_{2}^{2}}\right)=\frac{1}{4}-\eta,
$$

a contradiction.

Proof of Theorem 3.1. Let $R \geq B_{1}$ be constant given by Lemma 3.4 for $r=B_{1}$. In virtue of (3.2) and (3.5) we have $g_{*}:=\inf _{x \in(0, R]} g(x) \in \mathbb{R}$. Put

$$
K=\|e\|_{1}+\left|g_{*}\right| \quad \text { and } \quad K^{*}=K\|e\|_{1}+\int_{A_{2}}^{R}|g(x)| \mathrm{d} x .
$$

It follows from (3.3) and Remark 3.2 that we can choose $\varepsilon \in\left\{\varepsilon_{n}\right\}_{n=1}^{\infty}$ such that $\varepsilon \in\left(0, A_{2}\right)$ and

$$
\begin{equation*}
\int_{\varepsilon}^{A_{2}} g(x) \mathrm{d} x>K^{*} \quad \text { and } \quad g(\varepsilon)>0 \tag{3.24}
\end{equation*}
$$

For $x \in \mathbb{R}$ and a.e. $t \in[0,2 \pi]$, put $f(t, x)=e(t)+\widetilde{g}(x)$, where

$$
\tilde{g}(x)=\left\{\begin{array}{cl}
0 & \text { if } x<0 \\
g(\varepsilon) \frac{x}{\varepsilon} & \text { if } x \in[0, \varepsilon) \\
g(x) & \text { if } x \in[\varepsilon, R) \\
g(R) & \text { if } x \geq R
\end{array}\right.
$$

Then $f \in \operatorname{Car}([0,2 \pi] \times \mathbb{R})$ fulfils (2.18)-(2.21), (2.23)-(2.25) with $a_{1}=a_{2}=0$, $b_{1}(t)=b_{2}(t)=e(t)-\bar{e}$ a.e. on $[0,2 \pi]$ and $m(t)=g_{*}+e(t)$ a.e. on $[0,2 \pi]$. Thus, by Theorem 2.11, the problem (1.1) has a solution $u$ such that $u\left(t_{u}\right) \in\left[A_{2}, B_{1}\right]$ for some $t_{u} \in[0,2 \pi]$ and $\left\|u^{\prime}\right\|_{\mathbb{C}} \leq K$. By Lemma 3.4 we have $u(t) \leq R$ for all $t \in[0,2 \pi]$. It remains to show that $u(t) \geq \varepsilon$ holds on $[0,2 \pi]$.

Let $t_{0}$ and $t_{1} \in[0,2 \pi]$ be such that

$$
u\left(t_{0}\right)=\min _{t \in[0,2 \pi]} u(t) \quad \text { and } \quad u\left(t_{1}\right)=\max _{t \in[0,2 \pi]} u(t)
$$

Clearly, $A_{2} \leq u\left(t_{1}\right) \leq R$. Due to the periodic boundary conditions we have $u^{\prime}\left(t_{0}\right)=u^{\prime}\left(t_{1}\right)=0$. Now, multiplying the differential relation $u^{\prime \prime}(t)=e(t)+$ $\widetilde{g}(u(t))$ by $u^{\prime}(t)$ and integrating over $\left[t_{0}, t_{1}\right]$, we get

$$
0=\int_{t_{0}}^{t_{1}} u^{\prime \prime}(t) u^{\prime}(t) \mathrm{d} t=\int_{t_{0}}^{t_{1}} e(t) u^{\prime}(t) \mathrm{d} t+\int_{t_{0}}^{t_{1}} \widetilde{g}(u(t)) u^{\prime}(t) \mathrm{d} t
$$

i.e.

$$
\int_{u\left(t_{0}\right)}^{u\left(t_{1}\right)} \widetilde{g}(x) \mathrm{d} x=-\int_{t_{0}}^{t_{1}} e(t) u^{\prime}(t) \mathrm{d} t \leq K\|e\|_{1} .
$$

Further,

$$
\int_{u\left(t_{0}\right)}^{A_{2}} \widetilde{g}(x) \mathrm{d} x \leq K\|e\|_{1}+\int_{A_{2}}^{R}|\widetilde{g}(x)| \mathrm{d} x=K^{*}
$$

which, with respect to (3.24), is possible only if $u\left(t_{0}\right) \geq \varepsilon$. Thus, $u$ is a solution to (3.1).
3.5. Theorem. If $e$ is essentially bounded from below on $[0,2 \pi]$, then the condition (3.8) can be omitted in Theorem 3.1.

Proof. By (3.10) there is $A_{2} \in\left(0, A_{1}\right)$ such that $e(t)+g\left(A_{2}\right) \geq 0$ a.e. on [ $0,2 \pi]$. Taking this $A_{2}$ we can argue as in the proof of Theorem 3.1 with the
only difference that $b_{2}(t)=0$ a.e. on $[0,2 \pi]$, which implies $A_{2}=B_{2}$ in the application of Theorem 2.11.

Let us complete the above existence results by an easy consequence of Theorem 2.8.
3.6. Theorem. Assume that (3.2), (3.7), (3.8) and (3.9) are satisfied and let $A_{2} \geq B_{1}$. Then (3.1) has a solution $u$ such that

$$
\begin{equation*}
A_{1} \leq u(t) \leq B_{2} \text { on }[0,2 \pi] \tag{3.25}
\end{equation*}
$$

Proof. For a.e. $t \in[0,2 \pi]$ define

$$
f(t, x)=e(t)+\left\{\begin{array}{cl}
g\left(A_{1}\right) & \text { if } x<A_{1} \\
g(x) & \text { if } x \geq A_{1}
\end{array}\right.
$$

Then $f \in \operatorname{Car}([0,2 \pi] \times \mathbb{R})$ fulfils (2.18)-(2.23) with $a_{1}=a_{2}=0, b_{1}(t)=$ $b_{2}(t)=e(t)-\bar{e}$ a.e. on $[0,2 \pi]$. Hence, by Theorem 2.8, the problem (1.1) has a solution $u$ satisfying (3.25), which means that $u$ is a solution to (3.1).
3.7. Example. Notice that the function

$$
g(x)=-0.24 x+\frac{1+\sin \left(\frac{\pi}{x}\right)}{x}, \quad x \in(0, \infty)
$$

verifies the assumptions (3.2), (3.3), (3.5) and (3.6) of Theorem 3.1, while it does not satisfy the condition (3.4) required by Omari and Ye in [13, Theorem 1.2]. Since $\lim _{x \rightarrow \infty} g(x)=-\infty$, we can find for any $e \in \mathbb{L}[0,2 \pi]$ and any $B_{2}>0$ a number $A_{1} \in\left[B_{2}, \infty\right)$ such that $g$ fulfils (3.7) with any $B_{1} \in\left(A_{1}, \infty\right)$. Thus, by Theorem 3.5, if $e$ is essentially bounded from below, the problem

$$
\begin{equation*}
u^{\prime \prime}=-0.24 u+\frac{1+\sin \left(\frac{\pi}{u}\right)}{u}+e(t), \quad u(0)=u(2 \pi), \quad u^{\prime}(0)=u^{\prime}(2 \pi) \tag{3.26}
\end{equation*}
$$

has at least one positive solution. Provided $e$ is not essentially bounded from below, we will use Theorem 3.1 which requires that $g$ fulfil (3.8). Let us restrict ourselves to $e \in \mathbb{L}[0,2 \pi]$ such that $\bar{e}=-7$. We can show that the equation $g(x)=7$ has exactly 5 roots $x_{i}, i=1,2, \ldots, 5$, in the interval $[0.12, \infty)$. In particular, we have $x_{1} \approx 0.125587, x_{2} \approx 0.142891, x_{3} \approx 0.165230$, $x_{4} \approx 0.206177, x_{5} \approx 0.236265, g(x)>7$ on $\left(x_{2}, x_{3}\right) \cup\left(x_{4}, x_{5}\right)$ and $g(x)<7$ on $\left(x_{1}, x_{2}\right) \cup\left(x_{3}, x_{4}\right) \cup\left(x_{5}, \infty\right)$. Let

$$
\begin{equation*}
d<\frac{x_{3}-x_{2}}{2} \tag{3.27}
\end{equation*}
$$

and assume in addition that $\|e-\bar{e}\|_{\mathbb{L}} \leq \frac{3}{\pi} d$. We have $x_{2}-x_{1}>d$ and $x_{i+1}-x_{i}>2 d$ for $i=2,3,4$. We can apply Theorem 3.6 to obtain the existence of solutions $u_{1}$ and $u_{2}$ of the problem (3.1) such that $u_{1}(t) \in\left[x_{2}-d, x_{2}+d\right]$ and $u_{2}(t) \in\left[x_{4}-d, x_{4}+d\right]$ on $t \in[0,2 \pi]$, i.e. $u_{1}(t)<u_{2}(t)$ on $[0,2 \pi]$. Moreover, by Theorem 3.1 there is another solution $u_{3}$ of (3.1) such that $u_{3}\left(t_{3}\right) \in\left[x_{3}-\right.$ $\left.d, x_{3}+d\right]$ for some $t_{3} \in[0,2 \pi]$. In virtue of (3.27) that means that $u_{3}$ can coincide neither with $u_{1}$ nor with $u_{2}$.
3.8. Remark. In Theorems 3.1 and 3.5 the assumption (3.3) is substantial. The existence theorem which concerns the case $A_{1} \geq B_{2}$ and does not need (3.3) has been proved in [17, Corollary 3.7].
